#### **INNOVATION ECONOMICS**

# Where is Silicon Valley?

Forecasting and mapping entrepreneurial quality

#### By Jorge Guzman<sup>1</sup> and Scott Stern<sup>1,2\*</sup>

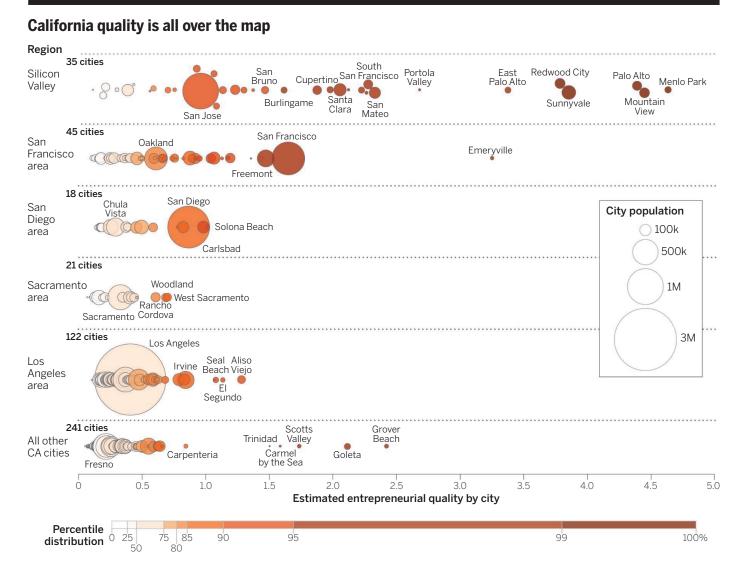

Ithough economists, politicians, and business leaders have long emphasized the importance of entrepreneurship (1, 2), defining and characterizing entrepreneurship has been elusive (3, 4). Researchers have been unable to systematically connect the type of highimpact entrepreneurship found in regions such as Silicon Valley with the overall incidence of entrepreneurship in the population (5-7). This has important implications: Researchers arrive at alternative conclusions about roles and patterns of entrepreneurship (8-10), and policy-makers are given conflicting recommendations about whether or how to promote entrepreneurship for economic and social progress (11, 12).

To break this impasse, we introduce a new method for studying the founding and growth of entrepreneurial ventures. Whereas

**POLICY** most prior studies have focused on the quantity of entrepreneur-

ial ventures (e.g., the number of new businesses per capita in a given region), we focus on characterizing their quality. Rather than assume that all ventures have an equal ex ante probability of success, our method allows us to estimate the probability of growth based on information publicly available at or near the time of founding.

We implement our approach using forprofit business registrations in California from 2001 to 2011 (13), combined with data from the U.S. Patent and Trademark Office and SDC Platinum [details on data and methods are in the supplementary materials (SM)]. We estimate outcomes on the basis of a small number of start-up characteristics: (i) firm name characteristics, including whether the firm name is eponymous [named after

the founder (14)], is short or long, is associated with local business activity or regionally traded clusters (e.g., dry cleaning versus manufactured goods), or is associated with a set of high-technology industry clusters (15, 16); (ii) how the firm is registered, including whether it is a corporation [rather than partnership or limited liability company (LLC)] and whether it is incorporated in Delaware (17); and (iii) whether the firm establishes control over formal intellectual property (IP) rights within 1 year of registration (18).

To ensure that our estimate reflects the quality of start-ups in a location rather than assuming that start-ups from a given location are associated with a given level of quality, we exclude location-specific measures from the set of observable start-up characteristics. **Estimating entrepreneurial quality by city.** Each bubble represents a city. Bubble size reflects city population. Bubble color varies according to quality scale at bottom of figure. Each row represents distinct geographic region. See SM.

We estimate entrepreneurial quality as the probability of achieving a meaningful growth outcome—defined as an initial public offering (IPO) or an acquisition (*19*) within 6 years of founding—as a function of these start-up characteristics. This predictive, location-agnostic algorithm can then be used to independently characterize the entrepreneurial quality of firms and locations.

**ESTIMATING ENTREPRENEURIAL QUAL-ITY.** We estimate entrepreneurial quality through a logit model with a randomly selected sample of 70% of all firms registered in 2001–2006 (keeping the other 30% as a test sample). Our model incorporates business registration and IP factors in a single regression, with all coefficients significant at the 5% level (20) (table S1). When we look at firm name characteristics, eponymous firms are more than 70% less likely to grow than noneponymous firms, whereas firms with short names are 50% more likely to grow than firms with long names, and firms that include words associated with hightechnology clusters are 92% more likely to grow than others. Looking at legal form and IP, corporations are >6 times more likely to grow than noncorporations, and firms with trademarks are >5 times more likely to grow than nontrademarked firms. Patenting and Delaware jurisdiction play an outsized role: Each alone is associated with a >25 times increase in the probability of growth relative to not being present. When both are present at the same time, there is nearly a 200 times increase in the probability of growth.

As a validation test, we estimate entrepreneurial quality for the test sample withheld from the original regression and so

<sup>&</sup>lt;sup>1</sup>Sloan School of Management, Massachusetts Institute of Technology, Cambridge, MA 02142, USA. <sup>2</sup>National Bureau of Economic Research, Cambridge, MA 02138, USA. \*E-mail: sstern@mit.edu

compare our predictions of entrepreneurial quality to the actual outcome distribution. Our estimate of entrepreneurial quality is strongly related to out-of-sample outcomes: 76% of all growth outcomes in the test sample are within the top 5% of the distribution of estimated entrepreneurial quality, with 56% drawn from the top 1% of that distribution (fig. S1). Highlighting the extreme uncertainty associated with entrepreneurship, growth is still rare: Even within the top 1% of estimated entrepreneurial quality, the average firm has only a 5% chance of realizing a growth outcome. This is consistent with recent findings that start-up growth is skewed relative to overall firm growth-Gibrat's law (21).

#### MAPPING ENTREPRENEUR-

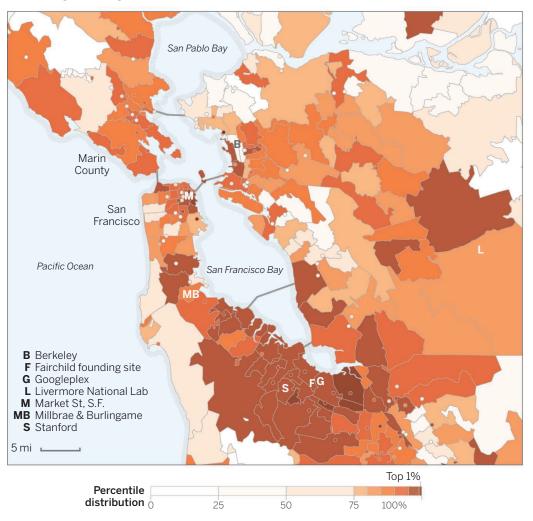

**SHIP.** The centerpiece of our analysis focuses on recent cohorts before a growth outcome has occurred (i.e., all start-ups from 2007 to 2011). We estimate the entrepreneurial quality for each firm and then calculate the average estimated quality of firms by city and, separately, by ZIP Code. These scores can be interpreted as the expected number of growth outcomes per 1000 start-ups in the 2007–2011 cohorts.

Average quality across municipalities is shown in the first figure. Silicon Valley stands out

from other regions across California: Startups in Menlo Park, Mountain View, Palo Alto, and Sunnyvale have 20 times the average quality of the median city and 90 times that of the lowest-ranked cities in California. Among large cities, San Francisco registers an entrepreneurial quality level nearly 8 times that of Fresno.

Entrepreneurial quality is mapped for the San Francisco Bay area at the ZIP Code level in the second figure. The quality of entrepreneurial activity is distinctively higher in the area that ranges just north of San Jose through San Francisco, with a contiguous mass of intense entrepreneurial quality from just southeast of Google (and the founding location of Fairchild) through Milbrae and Burlingame. In contrast, the Los Angeles region has a much lower level of entrepreneurial quality (fig. S2). Large economic areas can vary significantly in their quality. We investigated the statistical relation between

#### Better by the Bay

Mapping estimated entrepreneurial quality by ZIP Code. San Francisco Bay area. Dots indicate single-address ZIP Codes. See SM.

quality and quantity (fig. S3): At best, the relation is weak and noisy. Intriguingly, across regions, entrepreneurial quality is centered around research institutions, such as universities and national laboratories. Stanford is at the heart of Silicon Valley, and University of California (UC) Berkeley; Lawrence Livermore; Caltech; University of California, Los Angeles (UCLA); and UC Irvine each host a region of distinctive entrepreneurial quality.

**IMPLICATIONS.** By focusing on entrepreneurial quality, we can evaluate more clearly the role of location and institutions in firm growth. For example, our method allows us to estimate a locational entrepreneurship "premium" as the difference between realized and expected growth outcomes for a region. Between 2001 and 2006, Silicon Valley had 60% more actual growth events than predicted by our model, whereas Los Angeles registered 13% fewer than predicted. Our method can be extended to evaluate entrepreneurial quality at arbitrary levels of geographic aggregation (e.g., a specific street in Palo Alto) (fig. S4). This facilitates finegrained analysis of entrepreneurial dynamics (22), distinguishing empirically (although not causally) between locations at a high level of granularity.

Finally, beyond our characterization of Silicon Valley in the aggregate, our results highlight the role of research institutions as centers of entrepreneurial quality. Characterizing the two-way relation between entrepreneurial quality and scientific research activity is a promising agenda for future research. Although one would need to be cautious about using these estimates as a policy tool (for example, one could imagine "gaming" of various sorts), clarifying the conditions that facilitate positive growth outcomes has important implications for policy-makers and regional stakeholders.

#### IMMUNOLOGY

# There goes the macrophage neighborhood

Migrating dendritic cells disrupt lymph node macrophages and limit the immune response to secondary infection

#### By Heather D. Hickman

he lymph node is a highly structured organ optimized for generating adaptive immune responses. Lymph fluid carrying pathogens and their antigens from infected tissue is first distributed into a large cavity just beneath the node's surface, which is populated by a dense layer of specialized macrophages. These subcapsular sinus (SCS) macrophages filter incoming lymph, capture pathogens, and relay pathogen-derived antigen to B cells in subjacent follicles, provoking them to produce antibodies (see the figure). At the original infection site, migratory dendritic cells (DCs) are activated, acquire antigen, and deliver it to the node through the lymph, generating a secondary wave of immune cell activation. Until now, this influx of DCs has been viewed as beneficial to the host, as they activate T cells within the node's paracortex. However, on page 667 of this issue, Gaya et al. (1) demonstrate that incoming DCs can be harmful. These cells can disrupt the SCS macrophage layer and reduce the host's ability to mount a humoral (antibody) response to a secondary pathogen.

Resident antigen-presenting cells in the lymph node are commonly classified into two major subsets: DCs and macrophages. Both populations are a complex, heterogeneous mixture of cells with somewhat nebulous differences and overlapping capabilities. Even so, it is clear that different cellular subsets within each population preferentially localize to distinct regions of the lymph node where they can optimally activate discrete aspects of immune responses (2). For example,  $CD8\alpha$  DCs reside in the interior of the node, are efficient exogenous antigen gatherers, and are needed for optimal T cell activation after viral infection (3). Several subsets of DCs are not present (in appreciable numbers) in steadystate lymph nodes, but traffic to nodes from peripheral tissue sites after infection or inflammation. Because activation, and particularly migration, take time, hours to days may elapse before immigrant DCs can influence the immune response. It is unclear how these migratory DCs precisely navigate nodal architecture to situate themselves in the node's interior; however, their arrival is essential for eliciting maximal T cell responses to many pathogens (4).

SCS macrophages, typically distinguished by the expression of the cell surface marker CD169 and the absence of F4/80 (found on medullary macrophages in the node), form a sessile, carpet-like layer along the floor of the SCS. After subcutaneous injection of viruses or antigen-antibody immune complexes, SCS macrophages transfer antigen on cellular processes to closely apposed B cells that lack direct access to SCS contents

# "The evolutionary advantage of reduced responses to ... secondary challenges is puzzling."

(5-8). This antigen-capture process both activates B cells and removes infectious material from the lymph, preventing entry into the bloodstream. Accordingly, depletion of SCS macrophages from the node before infection can result in failure to control pathogen dissemination, leading to the infection of distal organs (6, 9, 10).

Although carefully scrutinized previously with primary infection models, the behavior and function of SCS macrophages have not been systematically followed for extended periods after infection. To close this gap, Gaya et al. used sophisticated techniques to image skin-draining murine lymph nodes 1 week after cutaneous infection with a variety of pathogens (including Staphylococcus, group B Streptococcus, and vaccinia virus). Intriguingly, the authors observed fragmentation of the SCS macrophage layer after infection with any of the pathogens, with as much as 80% of the layer disrupted. Gaya et al. also assessed the ability of various additional stimuli to deplete the SCS macrophage layer. Whereas the injection of inert beads or dead

# Estimated Entrepreneurial Quality vs. Entrepreneurial Quantity

# Fig. S3. Estimated entrepreneurial quality vs. entrepreneurial quantity.

The micro-geography of estimated entrepreneurial quality. This figure renders the estimated entrepreneurial quality of start-ups founded in 2010 and 2011 within a two-block length of El Camino Real in Palo Alto, CA. The blocks were selected due to the relatively high incidence of new business registrants within this location.

Fig. S4. The microgeography of entrepreneurial quality.

#### I. California Business Registration Records

Business registration records are a potentially rich and systematic data source for entrepreneurship and business dynamics. While it is possible to found a new business without business registration (e.g., a sole proprietorship), the benefits of registration are substantial, including limited liability, protection of the entrepreneur's personal assets, various tax benefits, the ability to issue and trade ownership shares, credibility with potential customers, and the ability to deduct expenses. Among business registrants, there are several categories, and the precise rules governing each category varies by jurisdiction and time. This study focuses on the state of California from 2001 to 2011, at which point one could register the following: corporations, limited liability companies, limited liability partnerships, limited partnerships, and general partnerships [see (1) for further information].

The data in this paper comes from the California Secretary of State (http://kepler.sos.ca.gov, data received on January 24, 2014) containing three files, two for corporation records and one for partnerships (which also include LLCs). The first corporation file contains a master record of all firms ever registered in California as that record exists at the moment of extraction; the second corporation file contains a record of all changes to each file on record. The corporation master file includes the following fields: corporation id; incorporation date; tax status (nonprofit or for profit); firm status (active, deceased, merged, etc.); jurisdiction (California or another U.S. state); address; firm name; name of president or manager; address of the principal office (for firms foreign to California); and California county (for California firms). The partnership master file includes the following fields: a firm id; registration date; firm status (active, deceased, merged, etc.); jurisdiction (California, or another U.S. state); address; address of the principal office; and up to two general partners or managers.

After combining these files, we generate unique firm identifiers. For this paper, we select a data set of the for-profit firms first registered in California from 1 January 2001 to 31 December 2011, satisfying one of the following two conditions: (i) for-profit firms whose jurisdiction is California and (ii) for-profit Delaware firms whose main office is in California. Table S2 lists the number of observations in our data set for each annual cohort year from 2001 to 2011. It is useful to note that, for those firms registered in Delaware, we use the year they registered in California as their founding date. Both the links to the underlying data and the program files used to construct the data set are available through links in the Materials section.

As a final note, this paper uses a subset of the business registration records that we have now gathered from several states, including Massachusetts, Texas, Florida, Washington, and New York. Although our evaluation of these additional states is at a more preliminary stage, we have found very similar qualitative findings in terms of the impact of factors observable at or near the time of registration on subsequent growth outcomes and the ability of these models to offer detailed characterization of growth entrepreneurship clusters (e.g., the identification of the role of the Route 128 corridor and the Kendall Square area near MIT for growth entrepreneurship in Massachusetts). See Guzman and Stern (2) for further details.

Year	N*	Share of Total	<b>Cumulative Share</b>
2001	102,350	6.44	6.44
2002	117,776	7.41	13.84
2003	130,718	8.22	22.06
2004	150,680	9.47	31.54
2005	167,186	10.51	42.05
2006	167,236	10.52	52.56
2007	171,675	10.79	63.36
2008	156,165	9.82	73.18

2010	139,968	8.80	90.89
2011	144,906	9.11	100

**Table S2. Number of observations per year.** N is the number of observations after limiting the sample to for-profit firms registered in California and for-profit firms registered in Delaware with their main office in California.

#### **II. Data and Methods**

Our data set is drawn from the complete set of California business registrants from 2001 to 2011. Our analysis draws on the complete population of firms satisfying one of the following conditions: (i) a for-profit firm whose jurisdiction is in California or (ii) a for-profit firm whose jurisdiction is in Delaware but whose principal office address is in California. The resulting data set is composed of 1,590,370 observations. For each observation, we construct variables related to (i) the growth outcome for the startup, (ii) measures based on business registration observables and (iii) measures based on external observables that can be linked to the startup.

Growth outcome. The growth outcome utilized in this paper, Growth, is a dummy variable equal to 1 if the startup achieves an initial public offering (IPO) or is acquired at a meaningful positive valuation within 6 years of registration. Both outcomes, IPO and acquisitions, are drawn from Thomson Reuters SDC Platinum (3). Although the coverage of IPOs is likely to be nearly comprehensive, the SDC data set excludes some acquisitions. However, although the coverage of significant acquisitions is not universal in the SDC data set, previous studies have "audited" the SDC data to estimate its reliability, finding a nearly 95% accuracy (4). We observe 501 positive growth outcomes for the 2001–2006 start-up cohorts), yielding a mean for Growth of 0.0006. The median acquisition price is \$155.8 million (ranging from a minimum of \$9.7 million to a maximum of \$21.6 billion). In our main results, we assign acquisitions with an unrecorded acquisitions price as a positive growth outcome, because an evaluation of those deals suggests that most reported acquisitions were likely in excess of \$5 million. In unreported specifications, we drop firms where the acquisition price is not reported; neither the pattern of coefficient estimates nor our qualitative findings regarding the geography of growth entrepreneurship is affected by this choice. All of our results are also robust to including firms registered in Delaware into cohorts associated with their initial Delaware registration date (rather than their California registration date).

*Start-up characteristics.* The core of the empirical approach is to map growth outcomes to observable characteristics of start-ups at or near the time of business registration. We develop two types of measures: (i) measures based on business registration observables and (ii) measures based on external indicators of start-up quality that are observable at or near the time of business registration. We review each of these in turn.

*Measures based on business registration observables.* We construct six measures of startup quality based on information directly observable from the business registration record. First, we create binary measures related to how the firm is registered, including *corporation*, whether the firm is a corporation (rather than partnership or LLC) and *Delaware jurisdiction*, whether the firm is incorporated in Delaware. *Corporation* is an indicator equal to 1 if the firm is registered as a corporation and 0 if it is registered either as an LLC or partnership.<sup>1</sup> In the period of 2001 to 2006, 0.13% of corporations achieve a growth outcome versus only 0.03% of noncorporations. *Delaware jurisdiction* is equal to 1 if the firm is registered under Delaware, but has its main office in California (all other foreign firms are dropped before analysis). Delaware jurisdiction is favorable for firms which, due to more complex operations, require more certainty in corporate law, but it is associated with extra costs and time to establish and maintain two registrations. Between 2001 and 2006, 4.5% of the sample registers in Delaware; 70% of firms achieving a growth outcome do so.

<sup>&</sup>lt;sup>1</sup>Previous research highlights performance differences between incorporated and unincorporated entrepreneurs (5).

Second, we create four measures that are based on the name of the firm, including a measure associated with whether the firm name is eponymous (named after the founder), is short or long, is associated with local industries (rather than traded), or is associated with a set of high-technology industry clusters.

Drawing on the recent work of Belenzon, Chatterji, and Daley (6), we use the firm and founder name to establish whether the firm name is eponymous (i.e., named after one or more of the founders). *Eponymy* is equal to 1 if the first, middle, or last name of the top managers is part of the name of the firm itself.<sup>2</sup> We require names be at least four characters to reduce the likelihood of making errors from short names. Our results are robust to variations of the precise calculation of eponymy (e.g., names with a higher or lower number of minimum letters). We have also undertaken numerous checks to assess the robustness of our name matching algorithm. 10% of the firms in our training sample are eponymous [an incidence rate similar to (6)], though less than 3% for whom growth equals one. It is useful to note that, while we draw on (6) to develop the role of eponymy as a useful start-up characteristic, our hypothesis is somewhat different than (6): we hypothesize that eponymous firms are likely to be associated with lower entrepreneurial quality. Whereas (6) evaluates whether serial entrepreneurs are more likely to invest and grow companies which they name after themselves, we focus on the cross-sectional difference between firms with broad aspirations for growth (and so likely avoid naming the firm after the founders) versus less ambitious enterprises, such as family-owned "lifestyle" businesses.

Our second measure relates to the length of the firm name. Based on our review of naming patterns of growth-oriented start-ups versus the full business registration database, a striking feature of growth-oriented firms is that the vast majority of their names are at most two words (plus perhaps one additional word to capture organizational form (e.g., "Inc."). Companies such as Google or Spotify have sharp and distinctive names, whereas more traditional businesses often have long and descriptive names (e.g., "Green Valley Home Health Care & Hospice, Inc."). We define *short name* to be equal to one if the entire firm name has three of less words, and zero otherwise. 13.5% of firms within the 2001–2006 period have a short name, but the incidence rate among growth firms is more than 36%. We have also investigated a number of other variants (allowing more or less words, evaluating whether the name is "distinctive" (in the sense of being both noneponymous and also not an English word). While these are promising areas for future research, we found that the three-word binary variable provides a useful measure for distinguishing entrepreneurial quality.

Finally, we construct two measures based on how the firm name reflects the industry or sector that the firm within which the firm is operating. To do so, we take advantage of two features of the U.S. Cluster Mapping Project, which categorizes industries into (i) whether that industry is primarily local (demand is primarily within the region) versus traded (demand is across regions) and (ii) among traded industries, a set of 51 traded clusters of industries that share complementarities and linkages (7). We augment the classification scheme from the U.S. Cluster Mapping Project with the complete list of firm names and industry classifications contained in Reference USA, a business directory containing more than 10 million firm names and industry codes for companies across the United States (8). Using a random sample of 1.5

<sup>&</sup>lt;sup>2</sup>For corporations, we consider top managers only the current president, for partnerships and LLCs, we allow for any of the two listed managers. The corporation president and two top partnership managers are listed in the business registration records themselves.

million Reference USA records, we create two indices for every word ever used in a firm name. The first of these indices measures the degree of localness, and is defined as the relative incidence of that word in firm names that are in local versus non-local industries

$$\rho_i = \frac{\sum_{j \in \{local firms\}} \mathbf{1}[w_i \subseteq name_j]}{\sum_{j \in \{non-local firms\}} \mathbf{1}[w_i \subseteq name_j]}).$$

We then define a list of Top Local Words, defined as those words that are (i) within the top quartile of  $\rho_i$  and (ii) have an overall rate of incidence greater than 0.01% within the population of firms in local industries (see Table S10 for the complete list). Finally, we define *local* to be equal to one for firms that have at least one of the Top Local Words in their name, and zero otherwise. Just more than 15% of firms have local names, although only 3% of firms for whom *growth* equals one. We undertake a similar exercise for the degree to which a firm name is associated with a high-technology cluster. We draw on firm names from industries include in three USCMP clusters: Aerospace Vehicles and Defense, Biopharmaceuticals, and Information Technology and Analytical Instruments. We then create a list of names, Top High-Technology Words, which includes those words within the top quartile of relative incidence within industries within these three clusters, and with an incidence greater than 0.01% within the population of firms within the high-technology clusters (see Table S11 for the complete list). *Technology* is defined as equal to one for firms that have at least one of the Top High-Technology Words in their name, and zero otherwise. Less than 1% of firms register a positive value, though 7.2% of growth firms do.

*Measures based on external observables.* We construct two measures related to start-up quality based on information in intellectual property data sources. Although this paper only measures external observables related to intellectual property, our approach can be utilized to measure other externally observable characteristics that may be related to entrepreneurial quality (e.g., measures related to the quality of the founding team listed in the business registration, or measures of early investments in scale (e.g., a Web presence).

Building on prior research matching business names to intellectual property (9, 10), we rely on a name-matching algorithm connecting the firms in the business registration data to external data sources. Importantly, because we match only on firms located in California, and because firms names legally must be "unique" within each state's company registrar, we are able to have a reasonable level of confidence that any "exact match" by a matching procedure has indeed matched the same firm across two databases. In addition, our main results use "exact name matching" rather than "fuzzy matching"; in small-scale tests using a fuzzy matching approach [the Levenshtein edit distance (11)], we found that fuzzy matching yielded a high rate of false positives due to the prevalence of similarly named but distinct firms (e.g., Capital Bank v. Capitol Bank, Pacificorp Inc v. Pacificare Inc.).

Our matching algorithm works in three steps.

First, we clean the firm name by:

- expanding eight common abbreviations ("Ctr.", "Svc.", "Co.", "Inc.", "Corp.", "Univ.", "Dept.", "LLC.") in a consistent way (e.g., "Corp." to "Corporation")
- removing the word "the" from all names
- replacing "associates" for "associate"

Second, we create measures of the firm name with and without the organization type, and with and without spaces. We then match each external data source to each of these measures of the firm name. The online appendix contains all of the data and annotated code for this procedure.

This procedure yields two variables. Our first measure of intellectual property captures whether the firm is in the process of acquiring patent protection during its first year of activity. *Patent* is equal to 1 if the firm holds a patent application in the first year. All patent applications and patent application assignments are drawn from the Google U.S. Patent and Trademark Office (USPTO) Bulk Download archive. We use patent applications, rather than granted patents, because patents are granted with a lag and only applications are observable close to the data of founding. Note that we include both patent applications that were initially filed by another entity (e.g., an inventor or another firm), as well as patent applications filed by the newly founded firm. While only 0.6% of the firms in 2001–2006 have a first-year patent, 39% of growth firms do.

Our second intellectual property measure captures whether a firm registers a trademark during its first year of business activity. *Trademark* is equal to 1 if a firm applied for a trademark within the first year, and 0 otherwise. We build this measure from the Stata-ready trademark DTA file developed by the USPTO Office of Chief Economist (12). Between 2001 and 2006, 0.7% of all firms register a trademark, while 33% of growth firms do.

Table S3. Summary statistics for training period (2001–2006). SD, standard deviation.

**Table S4. Summary statistics for training, test, and prediction samples.** Summary statistics for all samples used in all procedures. We build our model with data from 2001 to 2006, and separate the data randomly into a 70% training and a 30% test sample. Test results are robust, with 76% of the realized growth events in the top 5% of our predicted distribution. We then predict on 2007–2011 data. We are unable to use 2012 and 2013 data for prediction because patent applications are only observable 18 months after submission and at the time we retrieved our data sets less than 18 months had elapsed since December 31st, 2012, the last day of 2012.

#### **III. Entrepreneurial Quality Estimation**

Our approach combines three interrelated insights. First, because the challenges to reach a growth outcome as a sole proprietorship are formidable, a practical requirement for any growth-oriented entrepreneur is business registration. For the purposes of this study, we focus on the state of California and observe the full population of state business registrants using publicly available records.

Second, it is possible to measure informative characteristics of each firm at or close to the time of registration and so to distinguish among business registrants in terms of their entrepreneurial quality. These characteristics include the names of the firm and its president or managers, the firm's location, the firm's organization type and local jurisdiction, and whether the firm seeks a patent or trademark.

Finally, although growth outcomes are observed with a lag, we can create a mapping between the set of meaningful growth outcomes and characteristics observable near the time of founding ("start-up characteristics"). Our primary model, presented in the third column of Table S1, is a logistic regression based on a training sample of California business registrants from 2001 to 2006. For a firm *i* in region *j* initially registered during cohort year *t*, we can measure a growth outcome  $g_{i,j,t+s}$  that is realized within *s* years of founding as a function of start-up characteristics  $X_{i,j,t}$ :

$$\theta_{i,j,t} = 1000 \times P(g_{i,j,t+s}|X_{i,j,t})$$
  
$$\theta_{i,j,t} = 1000 \times f(\alpha + \beta X_{i,j,t})$$

We then calculate  $\hat{\theta}_{i,j,t}$ , our estimate of entrepreneurial quality equal to the growth probability of firm *i* located in location *j* and registered at time *t* (multiplied by 1000). We calculate  $\hat{\theta}_{i,j,t}$  for all firms in our sample, including firms in the 30% "test" sample from 2001 to 2006 as well as the "prediction" sample from 2007 to 2011. Table S3 contains summary statistics on our training period.

Our primary findings regarding the geography of entrepreneurial quality presented in Figures 1 and 2 and Figs. S1 to S3, and Table S1 are based on the prediction sample from 2007 to 2011<sup>3</sup>. We calculate  $\widehat{\Theta_{j,t}}$ , the average entrepreneurial quality of start-ups in *j* founded at *t* (multiplied by 1000), at two different levels of geographic aggregation: ZIP Code (five-digit) and city. We use the 482 California cities listed in the 2010 Census Incorporated Places and Minor Civil Subdivisions. Our procedures accounts for 86% of all firms registered within the period; misspellings ("Los Amgeles," "Palo Alato"), use of neighborhood names rather than city names (e.g., "Sherman Oaks"), or firms in unincorporated areas are excluded from the city-level analysis.

Table S7 shows summary statistics for estimated entrepreneurial quality at three levels of aggregation: firm-level, ZIP Code–level, and city-level. The mean of entrepreneurial quality is less than one, indicating that there is less than a one in a thousand chance of achieving a growth outcome. The distribution is highly skewed, even at the level of ZIP Codes and cities: For firms

<sup>&</sup>lt;sup>3</sup> The main regression used is presented in Table S1 with coefficients as incidence ratios, and Table S5 presents the actual regression coefficients. In table S6, we include robustness tests by running our model on the subsets of corporations and traded firms.

in cities within the top one percent of entrepreneurial quality, the probability of a growth outcome is nearly 10 times higher than the average firm in the population.

Finally, in Figure 1, we group the cities into six regions of interest: Silicon Valley, San Francisco, Sacramento, Los Angeles, San Diego, and Other cities. For Sacramento, Los Angeles, and San Diego, we define these regions according to the Census-defined Metropolitan Statistical Areas (MSA). To represent the difference between the Northern and Southern Bay Area, we define the San Francisco Area as the areas covered by San Francisco County, Alameda County, Contra Costa County, and Marin County. We define Silicon Valley as those cities in San Mateo and Santa Clara counties. Table S8 contains a list of regions and the counties that belong to each one in our definition.

One important concern in policy applications of this methodology, is that our measures might change incentives of firms, such that they try to "game" the result by select into high-quality measures they previously did not care about (e.g. changing its name form long to short). We note that this possibility, though real, is bounded by the incentives of the founders. For example, it is unlikely that a founder with no intention to grow would incur the significant yearly expense require to keep a registration in Delaware (which we estimate around \$1000). Similarly, firms that signal in their name being a local business (e.g. "Taqueria") are unlikely to change their names in ways that affect their ability to attract customers. Finally, we also note that any effects from "gaming" would be short-lived because, as low quality firms select into a specific measure the correlation between such measure and growth—and therefore the weight our prediction model would assign to it—weakens.
